- The icosahedral quasicrystal *HoMgZn*-

## II - The Hull as a Dynamical System

## **Point Sets**

### A subset $\mathcal{L} \subset \mathbb{R}^d$ may be:

- 1. Discrete.
- 2. *Uniformly discrete*:  $\exists r > 0$  s.t. each ball of radius *r* contains at most one point of  $\mathcal{L}$ .
- 3. *Relatively dense*:  $\exists R > 0$  s.t. each ball of radius *R* contains at least one points of  $\mathcal{L}$ .
- 4. A *Delone* set:  $\mathcal{L}$  is uniformly discrete and relatively dense.
- 5. *Finite Local Complexity (FLC)*:  $\mathcal{L} \mathcal{L}$  is discrete and closed.
- 6. *Meyer* set:  $\mathcal{L}$  and  $\mathcal{L} \mathcal{L}$  are Delone.

### **Point Sets and Point Measures**

 $\mathfrak{M}(\mathbb{R}^d)$  is the set of Radon measures on  $\mathbb{R}^d$  namely the dual space to  $C_c(\mathbb{R}^d)$  (continuous functions with compact support), endowed with the weak<sup>\*</sup> topology.

For  $\mathcal{L}$  a *uniformly discrete* point set in  $\mathbb{R}^d$ :

$$\nu := \nu^{\mathcal{L}} = \sum_{y \in \mathcal{L}} \delta(x - y) \quad \in \mathfrak{M}(\mathbb{R}^d) \; .$$

## **Point Sets and Tilings**

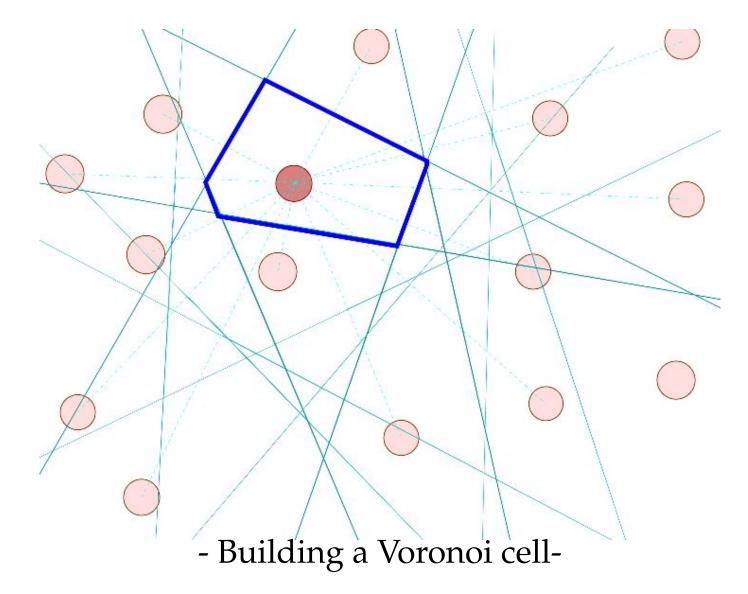

Given a tiling with finitely many tiles (*modulo translations*), a Delone set is obtained by defining a point in the interior of each (*translation equivalence class of*) tile.

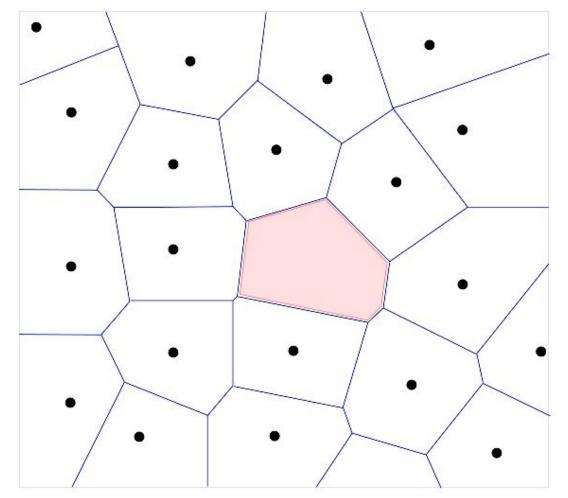

Conversely, given a Delone set, a tiling is built through the *Voronoi cells* 

$$V(x) = \{a \in \mathbb{R}^d ; |a - x| < |a - y|, \forall y \mathcal{L} \setminus \{x\}\}$$

1. V(x) is an *open convex polyhedron* containing B(x; r) and contained into  $\overline{B(x; R)}$ .

- 2. Two Voronoi cells touch face-to-face.
- 3. If  $\mathcal{L}$  is *FLC*, then the Voronoi tiling has finitely many tiles modulo translations.

- A Delone set and its Voronoi Tiling-

### The Hull

A point measure is  $\mu \in \mathfrak{M}(\mathbb{R}^d)$  such that  $\mu(B) \in \mathbb{N}$  for any ball  $B \subset \mathbb{R}^d$ . Its support is

1. Discrete.

- 2. *r*-*Uniformly discrete*: iff  $\forall B$  ball of radius r,  $\mu(B) \leq 1$ .
- 3. *R*-*Relatively dense*: iff for each ball *B* of radius *R*,  $\mu(B) \ge 1$ .

 $\mathbb{R}^d$  acts on  $\mathfrak{M}(\mathbb{R}^d)$  by translation.

**Theorem 1** The set of r-uniformly discrete point measures is compact and  $\mathbb{R}^d$ -invariant. Its subset of R-relatively dense measures is compact and  $\mathbb{R}^d$ -invariant.

**Definition 1** Given  $\mathcal{L}$  a uniformly discrete subset of  $\mathbb{R}^d$ , the Hull of  $\mathcal{L}$  is the closure in  $\mathfrak{M}(\mathbb{R}^d)$  of the  $\mathbb{R}^d$ -orbit of  $v^{\mathcal{L}}$ .

Hence the Hull is a *compact metrizable space* on which  $\mathbb{R}^d$  *acts by homeomorphisms*.

## **Properties of the Hull**

# If $\mathcal{L} \subset \mathbb{R}^d$ is *r*-uniformly discrete with Hull $\Omega$ then using compactness

- 1. each point  $\omega \in \Omega$  *is an r-uniformly discrete* point measure with support  $\mathcal{L}_{\omega}$ .
- 2. if  $\mathcal{L}$  is (r, R)-*Delone*, so are all  $\mathcal{L}_{\omega}$ 's.
- 3. if, in addition,  $\mathcal{L}$  is *FLC*, so are all the  $\mathcal{L}_{\omega}$ 's. Moreover then  $\mathcal{L} - \mathcal{L} = \mathcal{L}_{\omega} - \mathcal{L}_{\omega} \forall \omega \in \Omega$ .

**Definition 2** *The transversal of the Hull*  $\Omega$  *of a uniformly discrete set is the set of*  $\omega \in \Omega$  *such that*  $0 \in \mathcal{L}_{\omega}$ .

**Theorem 2** If  $\mathcal{L}$  is FLC, then its transversal is completely discontinuous.

## Local Isomorphism Classes and Tiling Space

A *patch* is a finite subset of  $\mathcal{L}$  of the form

$$p = (\mathcal{L} - x) \cap \overline{B(0, r_1)} \qquad x \in \mathcal{L} \,, \, r_1 \ge 0$$

Given  $\mathcal{L}$  a repetitive, FLC, Delone set let  $\mathcal{W}$  be its set of finite patches: it is called the *the*  $\mathcal{L}$ -*dictionary*.

A Delone set (or a Tiling)  $\mathcal{L}'$  is *locally isomorphic* to  $\mathcal{L}$  if it has the same dictionary. The *Tiling Space* of  $\mathcal{L}$  is the set of *Local Isomorphism Classes* of  $\mathcal{L}$ .

**Theorem 3** *The Tiling Space of*  $\mathcal{L}$  *coincides with its Hull.* 

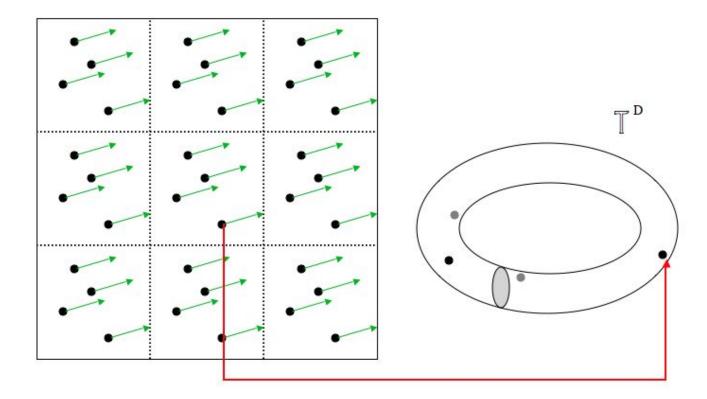

## Minimality

 $\mathcal{L}$  is *repetitive* if for any finite patch p there is R > 0 such that each ball of radius R contains an  $\epsilon$ -approximant of a translated of p.

**Theorem 4**  $\mathbb{R}^d$  acts minimaly on  $\Omega$  if and only if  $\mathcal{L}$  is repetitive.

## Examples

- 1. *Crystals* :  $\Omega = \mathbb{R}^d / \mathcal{T} \simeq \mathbb{T}^d$  with the quotient action of  $\mathbb{R}^d$  on itself. (Here  $\mathcal{T}$  is the translation group leaving the lattice invariant.  $\mathcal{T}$  is isomorphic to  $\mathbb{Z}^D$ .) The transversal is a finite set (number of point per unit cell).
- Impurities in Si : let L be the lattices sites for Si atoms (it is a Bravais lattice). Let A be a finite set (alphabet) indexing the types of impurities.
  The transversal is X = A<sup>Z<sup>d</sup></sup> with Z<sup>d</sup>-action given by shifts.
  The Hull Ω is the mapping torus of X.

- The Hull of a Periodic Lattice -

## Quasicrystals

Use the *cut-and-project* construction:

$$\mathbb{R}^d \simeq \mathcal{E}_{\parallel} \xleftarrow{\pi_{\parallel}} \mathbb{R}^n \xrightarrow{\pi_{\perp}} \mathcal{E}_{\perp} \simeq \mathbb{R}^{n-d}$$

 $\mathcal{L} \stackrel{\pi_{\parallel}}{\longleftarrow} \tilde{\mathcal{L}} \stackrel{\pi_{\perp}}{\longrightarrow} W \quad ,$ 

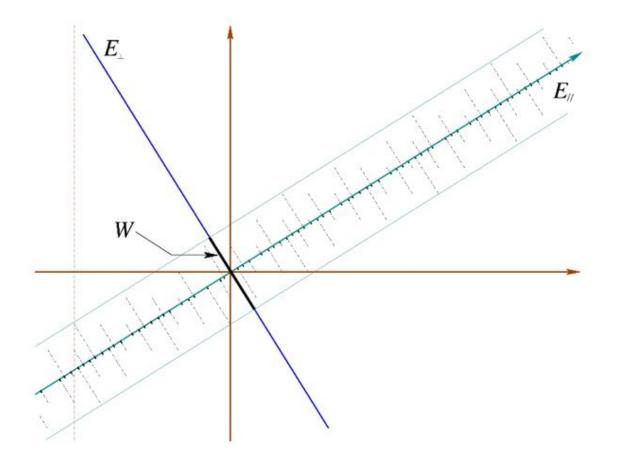

Here

1.  $\tilde{\mathcal{L}}$  is a *lattice* in  $\mathbb{R}^n$ ,

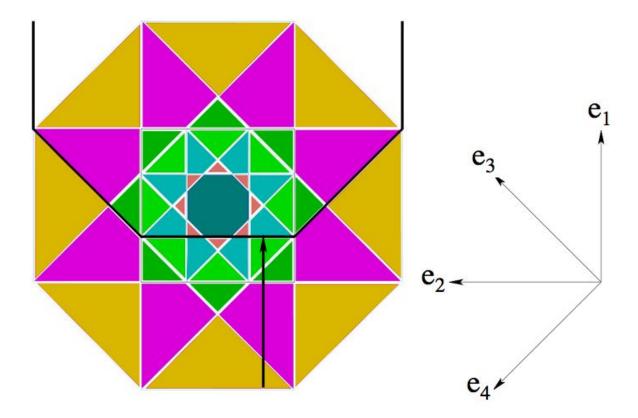

2. the *window W* is a compact polytope.

3.  $\mathcal{L}$  is the *quasilattice* in  $\mathcal{E}_{\parallel}$  defined as

 $\mathcal{L} = \{\pi_{\parallel}(m) \in \mathcal{E}_{\parallel}; m \in \tilde{\mathcal{L}}, \pi_{\perp}(m) \in W\}$ 

- The cut-and-project construction -

- The transversal of the Octagonal Tiling is completely disconnected -

## III - Branched Oriented Flat Riemannian Manifolds

### Laminations and Boxes

A *lamination* is a foliated manifold with  $C^{\infty}$ -structure along the leaves but only finite  $C^{0}$ -structure transversally. The *Hull of a Delone set is a lamination* with  $\mathbb{R}^{d}$ -orbits as leaves.

If  $\mathcal{L}$  is a *FLC, repetitive, Delone* set, with Hull  $\Omega$  a *box* is the home-omorphic image of

 $\phi:(\omega,x)\in F\times U\mapsto \tau^{-x}\omega\in\Omega$ 

if *F* is a clopen subset of the transversal,  $U \subset \mathbb{R}^d$  is open and  $\tau$  denotes the  $\mathbb{R}^d$ -action on  $\Omega$ .

A *quasi-partition* is a family  $(B_i)_{i=1}^n$  of boxes such that  $\bigcup_i \overline{B_i} = \Omega$  and  $B_i \cap B_j = \emptyset$ .

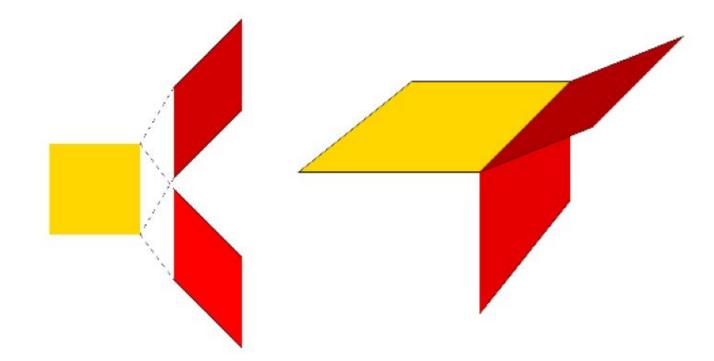

**Theorem 5** *The Hull of a FLC, repetitive, Delone set admits a finite quasi-partition. It is always possible to choose these boxes as*  $\phi(F \times U)$  *with U a d-rectangle.* 

### **Branched Oriented Flat Manifolds**

Flattening a box decomposition along the transverse direction leads to a *Branched Oriented Flat manifold*. Such manifolds can be built from the tiling itself as follows

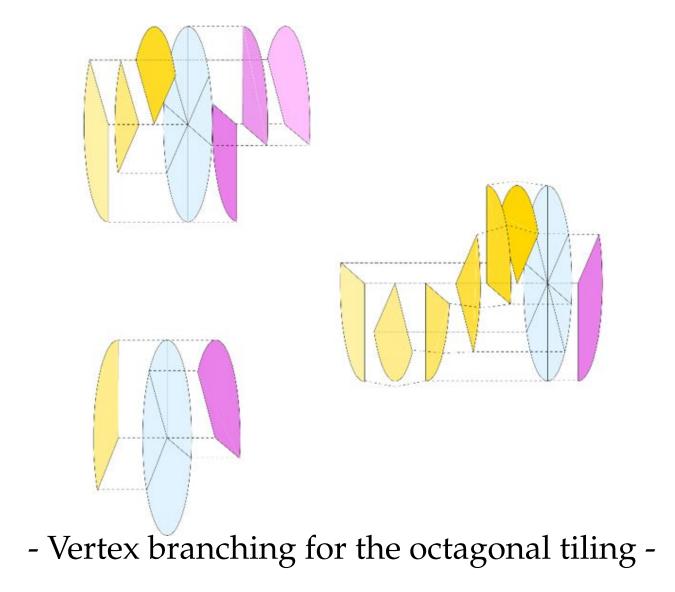

#### Step 1:

- 1. *X* is the disjoint union of all *prototiles*;
- 2. glue prototiles  $T_1$  and  $T_2$  along a face  $F_1 \subset T_1$  and  $F_2 \subset T_2$  if  $F_2$  is a translated of  $F_1$  and if there are  $x_1, x_2 \in \mathbb{R}^d$  such that  $x_i + T_i$  are tiles of  $\mathcal{T}$  with  $(x_1 + T_1) \cap (x_2 + T_2) = x_1 + F_1 = x_2 + F_2$ ;
- 3. after identification of faces, *X* becomes a *branched oriented flat manifold* (BOF) *B*<sub>0</sub>.

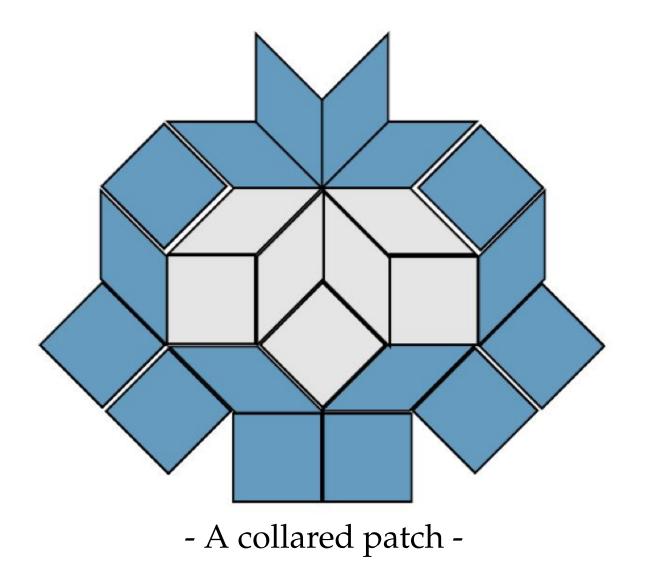

- Branching -

#### Bologna August 30th 2008

### Step 2:

- 1. Having defined the patch  $p_n$  for  $n \ge 0$ , let  $\mathcal{L}_n$  be the subset of  $\mathcal{L}$  of points centered at a translated of  $p_n$ . By repetitivity this is a FLC repetitive Delone set too. Its prototiles are tiled by tiles of  $\mathcal{L}$  and define a finite family  $\mathfrak{P}_n$  of patches.
- 2. Each patch in  $\mathcal{T} \in \mathfrak{P}_n$  will be collared by the patches of  $\mathfrak{P}_{n-1}$  touching it from outside along its frontier. Call such a patch *modulo translation* a *a collared patch* and  $\mathfrak{P}_n^c$  their set.
- 3. Proceed then as in Step 1 by replacing prototiles by collared patches to get the BOF-manifold  $B_n$ .
- 4. Then choose  $p_{n+1}$  to be the collared patch in  $\mathfrak{P}_n^c$  containing  $p_n$ .

### Step 3:

- 1. Define a *BOF-submersion*  $f_n : B_{n+1} \mapsto B_n$  by identifying patches of order *n* in  $B_{n+1}$  with the prototiles of  $B_n$ . Note that  $Df_n = 1$ .
- 2. Call  $\Omega$  the *projective limit* of the sequence

$$\cdots \stackrel{f_{n+1}}{\to} B_{n+1} \stackrel{f_n}{\to} B_n \stackrel{f_{n-1}}{\to} \cdots$$

3.  $X_1, \dots X_d$  are the commuting constant vector fields on  $B_n$  generating local translations and giving rise to a  $\mathbb{R}^d$  action  $\tau$  on  $\Omega$ .

**Theorem 6** *The dynamical system* 

$$(\Omega, \mathbb{R}^d, \mathbf{T}) = \lim_{\leftarrow} (B_n, f_n)$$

obtained as inverse limit of branched oriented flat manifolds, is conjugate to the Hull of the Delone set of the tiling T by an homemorphism.

# IV - Cohomology and K-Theory

## Čech Cohomology of the Hull

Let  $\mathcal{U}$  be an *open covering* of the Hull. If  $U \in \mathcal{U}, \mathcal{F}(U)$  is the space of integer valued locally constant function on U.

For  $n \in \mathbb{N}$ , the *n*-chains are the element of  $C^n(\mathcal{U})$ , namely the *free abelian group* generated by the elements of  $\mathcal{F}(U_0 \cap \cdots \cap U_n)$  when the  $U_i$  varies in  $\mathcal{U}$ . A differential is defined by

$$d: C^{n}(\mathcal{U}) \mapsto C^{n+1}(\mathcal{U})$$
$$df(\bigcap_{i=0}^{n+1} U_{i}) = \sum_{j=0}^{n} (-1)^{j} f(\bigcap_{i:i\neq j} U_{i})$$

Bologna August 30th 2008

This defines a *complex* with cohomology  $\check{H}^{n}(\mathcal{U},\mathbb{Z})$ . The Čech cohomology group of the Hull  $\Omega$  is defined as

$$\check{H}^{n}(\Omega,\mathbb{Z}) = \lim_{\to \mathcal{U}} \check{H}^{n}(\mathcal{U},\mathbb{Z})$$

with ordering given by *refinement* on the set of open covers.

## Longitudinal (co)-Homology

J. Bellissard, R. Benedetti, J.-. Gambaudo, Commun. Math. Phys., **261**, (2006), 1-41. J. Kaminker, I. Putnam, Michigan Math. J., **51**, (2003), 537-546. M. Benameur, H. Oyono-Oyono, C. R. Math. Acad. Sci. Paris, **334**, (2002), 667-670.

#### The Homology groups are defined by the inverse limit

$$H_*(\Omega, \mathbb{R}^d) = \lim_{\leftarrow} (H_*(B_n, \mathbb{R}), f_n^*)$$

**Theorem 7 (JB, Benedetti, Gambaudo**) The homology group  $H_d(\Omega, \mathbb{R}^d)$  admits a canonical positive cone induced by the orientation of  $\mathbb{R}^d$ , isomorphic to the affine set of positive  $\mathbb{R}^d$ -invariant measures on  $\Omega$ .

The cohomology groups are defined by the direct limit

 $H^*(\Omega, \mathbb{R}^d) = \lim_{\to} (H^*(B_n, \mathbb{R}), f_n^*)$ 

The following result is known as the *Gap labeling Theorem* and was proved simultaneously by KAMINKER-PUTNAM, BENAMEUR & OYONO-OYONO, JB-BENDETTI-GAMBAUDO. It is an extension of the *Connes index theorem* for foliations

**Theorem 8** If  $\mathbb{P}$  is an  $\mathbb{R}^d$ -invariant probability on  $\Omega$ , then the pairing with  $H^d(\Omega, \mathbb{R}^d)$  satisfies

$$\langle \mathbb{P} | H^d(\Omega, \mathbb{R}^d) \rangle = \int_{\Xi} d\mathbb{P}_{\mathrm{tr}} \ C(\Xi, \mathbb{Z})$$

where  $\Xi$  is the transversal,  $\mathbb{P}_{tr}$  is the probability on  $\Xi$  induced by  $\mathbb{P}$  and  $C(\Xi, \mathbb{Z})$  is the space of integer valued continuous functions on  $\Xi$ .

## Pattern-Equivariant Cohomology

J. KELLENDONK, J. Phys. A36, (2003), 5765-5772. J. KELLENDONK, I. PUTNAM, Math. Ann. 334, (2006), 693-711. L. SADUN, Pattern-Equivariant Cohomology with Integer Coefficients (2007)

Let  $\mathcal{L}$  be an FLC, repetitive Delone set in  $\mathbb{R}^d$ . A function  $f : \mathbb{R}^d \mapsto X$  is  $\mathcal{L}$ -pattern-equivariant if there is r > 0 such that f(x) = f(y) whenever  $B(0;r) \cap (\mathcal{L} - x) = B(0;r) \cap (\mathcal{L} - y)$ .

The Voronoi tiling of  $\mathcal{L}$  can be seen as a *chain complex*, with tiles being the *d*-cells, and their *k*-faces being the *k*-cells.

A *k-cochain* with integer cœfficients is then a linear map  $\alpha$  defined on the free abelian group of *k*-chains with values in  $\mathbb{Z}$ .

Let  $C_{\mathcal{P}}^k(\mathcal{L})$  be the abelian group of  $\mathcal{L}$ -pattern equivariant *k*-cochains. The usual coboundary operator (*de Rham differential*)

 $d_n: C^n_{\mathcal{P}}(\mathcal{L}) \mapsto C^{n+1}_{\mathcal{P}}(\mathcal{L})$ 

defines the *L*-pattern equivariant cohomology denoted by

 $H^k_{\mathcal{P}}(\mathcal{L},\mathbb{Z}) = \operatorname{Ker} d_n / \operatorname{Im} d_{n-1}$ 

## The PV-Cohomology

J. Bellissard, J.Savinien, *arXiv*: 0705.2483, (2007).

Each cell of the *Voronoi complex* is punctured. The set  $\mathcal{L}_S$  of such punctures defines the *simplicial transversal*  $\Xi_S$ . An equivalent class, modulo translation, of *n*-cell  $\sigma$  defines a compact subset  $\Xi_S(\sigma)$ .  $\chi_\sigma$  denotes the characteristic function of  $\Xi_S(\sigma)$ .

If  $\sigma$  is such a cell and  $\tau$  belongs to its boundary, then there is a unique vector  $x_{\sigma\tau}$  joining the puncture of  $\tau$  to the one of  $\sigma$ . Correspondingly the translation  $T^{x_{\sigma\tau}}$  in the Hull sends  $\Xi_s(\tau)$  into a part of  $\Xi_s(\tau)$ , defining the translation operator

$$\theta_{\sigma\tau} = \chi_{\sigma} T^{\chi_{\sigma\tau}} \chi_{\tau}$$

where  $\chi_{\sigma}$  denotes the characteric function of  $\Xi_s(\sigma)$ .

Bologna August 30th 2008

A *PV-n-cochain* will be a group homomorphism from the group of (oriented) *n*-chains on the BOF manifold  $B_0$  into the group  $C(\Xi_s, \mathbb{Z})$ . The Pimsner differential is defined by

$$df(\sigma) = \sum_{\tau \in \partial \sigma} [\sigma:\tau] f(\tau) \circ \theta_{\sigma\tau}$$

Here  $[\sigma : \tau]$  denoted the *incidence number* of  $\tau$  relative to  $\sigma$ . The associate cohomology is  $H^n_p(B_0, C(\Xi_s, \mathbb{Z}))$ .

## Cohomology and *K*-theory

The main topological property of the Hull (or tiling psace) is summarized in the following

**Theorem 9** (*i*) The various cohomologies, Čech, longitudinal, patternequivariant and PV, are isomorphic. (*ii*) There is a spectral sequence converging to the K-group of the Hull with page 2 given by the cohomology of the Hull. (*iii*) In dimension  $d \leq 3$  the K-group coincides with the cohomology.

- 1. *Tilings* can be equivalently be represented by *Delone sets* or *point measures*.
- 2. The *Hull* allows to give tilings the structure of a *dynamical system* with a transversal.
- 3. This dynamical system can be seen as a *lamination* or, equivalently, as the *inverse limit* of *Branched Oriented Flat Riemannian Manifolds*.

- 4. The Čech cohomology is equivalent to the longitudinal one, obtained by inverse limit, to the pattern-equivariant one or to the Pimsner cohomology are equivalent *Cohomology* of the Hull. The *K*-group of the Hull can be computed through a spectral sequence with the cohomology in page 2.
- 5. In maximum degree, the *Homology* gives the family of *invariant measures* and the *Gap Labelling Theorem*.
